Post-menopausal female with non-relapsed, ER+ breast cancer, and
Was lymph node negative, and
Is completing five (5) years of tamoxifen therapy, and
Patient must be eligible for consideration of extended endocrine therapy based on published clinical trial data or practice guidelines, and
Physician or patient is concerned about continuing anti-hormonal therapy because of documented meaningful toxicity or possible significant patient-specific side effects, and
The test results will be discussed with the patient (including the limitations of the testing method, the risks and benefits of either continuing or stopping the therapy based on the test, and current cancer management guidelines).

Claims for BCI testing will be denied when testing does not meet all of the above criteria.
Summary of Evidence

The body of evidence for the adjuvant endocrine treatment of ER+ breast cancer is continuing to evolve. Most recently, with the results of the ATLAS and aTTom trials, tamoxifen for an additional 5 years of adjuvant therapy has been added to the standard of care regimens as a NCCN recommendation to reduce late recurrences (defined as cancer recurring after 5 years of therapy).

The BCI assay (which was initially developed before ATLAS and aTTom data was available), uses PCR to interrogate selected proliferation-related and endocrine signaling-related genes, and may identify a subset of postmenopausal women who are at increased risk of late relapses for ER+ breast cancer and who may derive a greater benefit from extended hormone therapy. Current guidelines recommend adjuvant hormone therapy for postmenopausal patients with ER+ disease consisting of tamoxifen for 10 years (5 years initially and then strong consideration for an additional 5 years based on ATLAS and aTTom trials), aromatase Inhibitor (AI) for 5 years (ATAC), tamoxifen for 5 years followed by AI for 5 years (MA.17), or AI for 2-3 years followed by tamoxifen to complete 5 years. Extended (> 5 years) hormone therapy in each scenario is based on large randomized trials. Although there can be significant side effects of these therapies in some women, generally the side affect profile is manageable when compared to the significant benefit of these interventions. The optimal sequence and duration of AI therapy, the benefit of tamoxifen after prolonged AI therapy, and result of tamoxifen use beyond 10 years remain unknown.

Although the BCI assay may identify a group of patients at highest risk of recurrence after 5 years post surgery it cannot be used independently without consideration of other clinical factors (such as age, tumor size and number of lymph nodes involved). A significant concern exists as to whether the assay can identify any group at such a low risk that it is safe to depart from a strong expert recommendation and safely stop therapy. Data from the prospective-retrospective review of the ATAC trial (trans-ATAC) shows a late recurrence risk in all patients, independent of risk category (BCI-H, BCI-I or BCI-L). Although the BCI-L group is lower than the others, it is still roughly 3.5% (but with 95% CI could be as high at 6.1%) and the annual risk of relapse steadily climbs in the years after stopping adjuvant endocrine therapy at 5 years. Given the substantial number of patients at risk in the BCI-Low group (over 60%), the total number of women at risk that may benefit from extended hormone therapy at the end of 5 years of tamoxifen therapy is not negligible.

Analysis of the prospective-retrospective review of MA.17 data, extended adjuvant therapy may be helpful in all groups studied. Although the H/I-low group did not meet statistical significance, the recurrence rate was decreased from 13% to 9% with the use of extended letrozole therapy with a relative risk reduction of 30%. In the H/I-High group the relative risk reduction was similar at 59%, which did meet statistical significance.

Analysis of Evidence
(Rationale for Determination)

Level of Evidence

Quality: Moderate

Strength: Limited

Weight: Limited

The risk BCI-C model developed from the trans-ATAC data provides a continuous risk predicted by the test. The risk curve is flat in only the very lowest BCI values. Starting around BCI of 2 (in the middle of the BCI-Low category), there is a linear increase in recurrence risk. At the 95% confidence interval (CI), the risk in some individuals categorized in the BCI-low group could be as high as 20%. Due to the data complexity, there is a significant possibility that a physician might consider all BCI-L patients at negligible risk, and thus not consider extended hormone therapy and consequently lead women from the NCCN recommended interventions. Given the low toxicity and low cost of extended therapy, the false sense of security could deny many women from lifesaving therapy.

In women who have received an AI for 5 years, data is lacking on the utility of extended adjuvant hormonal therapy.

The data defined benefit of the BCI test appears to be when a woman is having significant side effects or has other concerns regarding adjuvant tamoxifen therapy and is opposed to taking more than 5 years of tamoxifen or
starting on an AI (letrozole) after tamoxifen. If the toxicity or concern of extending hormone therapy is significant then it may be reasonable to use the BCI test to help make a risk/benefit decision with the patient on continued adjuvant endocrine therapy. In the majority of patients, the toxicity of extended hormone therapy is tolerable especially in those who already have been on adjuvant hormonal therapy for 5 years. Even with the small benefit in all patients the MA.17, ATLAS and aTTom trials all demonstrated benefit from longer endocrine therapy. These trials established that the generally low toxicity of hormone therapy allows its long-term usage.

**BCI Use for Newly Diagnosed Breast Cancer Patients:**
It is possible that the BCI assay could identify patients who would most benefit from chemotherapy in the upfront setting, but this benefit has not been adequately studied. In one observational study the BCI risk recurrence level correlated with complete response to chemotherapy, but this trial does not provide sufficient evidence to warrant consideration for decision making in the newly diagnosed breast cancer patient. Further data will need to be published before the benefit of BCI can be confirmed or refuted in this setting.

### Coding Information

**Bill Type Codes:**

Contractors may specify Bill Types to help providers identify those Bill Types typically used to report this service. Absence of a Bill Type does not guarantee that the policy does not apply to that Bill Type. Complete absence of all Bill Types indicates that coverage is not influenced by Bill Type and the policy should be assumed to apply equally to all claims.

023x Skilled Nursing - Outpatient

**Revenue Codes:**

Contractors may specify Revenue Codes to help providers identify those Revenue Codes typically used to report this service. In most instances Revenue Codes are purely advisory. Unless specified in the policy, services reported under other Revenue Codes are equally subject to this coverage determination. Complete absence of all Revenue Codes indicates that coverage is not influenced by Revenue Code and the policy should be assumed to apply equally to all Revenue Codes.
